# Architectural Approach to Software Protection

- Computer is divided to **observable** and **protected** parts
- Technologically possible: accessible memory but protected processor
- **Today**: making interction between processor and memory useless for learning program

Yury Lifshits (Steklov Inst. of Math) Oblivious RAM Tartu '06 1 / 20

## Outline

- 1 What Kind of Computer Are We Going To Construct?
- 2 Basic Solutions
- 3 Hierarchical Construction

Yury Lifshits (Steklov Inst. of Math) Oblivious RAM Tartu '06 3 / 20

## Computer Model

- Two parts: Memory and Processor
- Internal memory of Processor =  $c \log |\text{Memory}|$
- Interaction: **fetch**(address), **store**(address, value)
- Processor has access to random oracle
- Computation starts with a program and an input in Memory
- One step: fetch one cell - update value and Processor memory - store

## Oblivious Execution

We want to **hide**: order of accesses to cells of Memory

Oblivious execution:

For all programs of size  $m$  working in time  $t$   
order of fetch/store addresses is the same

Weaker requirement:

For all programs of size  $m$  working in time  $t$   
order of fetch/store addresses has the same distribution

Yury Lifshits (Steklov Inst. of Math) Oblivious RAM Tartu '06 6 / 20

## Naive Simulation

Simulation 1:

- 1 We store encrypted pairs (address,value) in memory cells
- 2 For every fetch/store we scan through **all** memory
  - Wrong address  $\Rightarrow$  just reencrypt and store
  - Right address  $\Rightarrow$  do the job  $\Rightarrow$  encrypt and store the result

Cost of simulation:  $tm$  time,  $m$  memory

Yury Lifshits (Steklov Inst. of Math) Oblivious RAM Tartu '06 8 / 20

## Square Root Solution (1)

We need to protect:  
Order of accesses  
Number of accesses

Memory = Main Part ( $m + \sqrt{m}$ ) | Shelter  $\sqrt{m}$

Idea:  
Divide computation in epochs of  $\sqrt{m}$  steps each  
On each original step make one fetch to the Main Part  
and scan through all the Shelter

## Square Root Solution (2)

Simulation 2:

- 1 Store input in the Main Part
- 2 Add  $\sqrt{m}$  dummy cells to the Main part
- 3 For every epoch of  $\sqrt{m}$  steps
  - Permute all cells in the Main Part (using permutation  $\pi$  from random oracle)
  - For each process( $i$ ) scan through the shelter. If  $i$ -th element is not founded, fetch it from  $\pi(i)$ , otherwise fetch next dummy cell
  - Update (obliviously) the Main Part using the Shelter values

Cost of simulation:  $t\sqrt{m}$  time,  $m + 2\sqrt{m}$  memory

## Buffer Solution (1): Oblivious Hash Table

Memory of initial program:  $(a_1, v_1), \dots, (a_m, v_m)$

- Take a hash function  $h : [1..m] \rightarrow [1..m]$
- Prepare  $m \times \log m$  table
- Put  $(a_i, v_i)$  to random free cell in  $h(a_i)$ -th column
- Home problem 4: Prove that the chance of overflow is less than  $1/m$

## Buffer Solution (2): Simulation

Restricted problem: assume that every cell accessed only once

Simulation 3:

- 1 Construct (obliviously) a hash table
- 2 For every step fetch( $i$ ) of initial program
  - Scan through  $h(i)$  column
  - Update the target cell

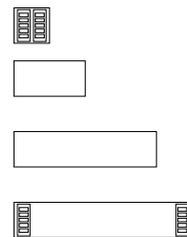

Cost of simulation:  $t \log m$  time,  $m \log m$  memory

## Outline

- 1 What Kind of Computer Are We Going To Construct?
- 2 Basic Solutions
- 3 Hierarchical Construction

## Data Structure

- $k$ -Buffer = table  $2^k \times k$
- Hierarchical Buffer Structure = 1-buffer,  $\dots$ ,  $\log t$ -buffer
- Initial position: input in last buffer, all others are empty

## Hierarchical Simulation

Simulation of processing cell  $i$ :

- 1 Scan through 1-buffer
- 2 For every  $j$  scan through  $h(i, j)$ -th column in  $j$ -buffer
- 3 Put the updated value to the first buffer

## Periodic Refreshing

Refreshing the data structure:

- 1 Every  $2^{l-1}$  steps unify  $j$ -th and  $j-1$ -th buffers
- 2 Delete doubles
- 3 Using new hash function put all data to  $j-th$  level

Invariant: For every moment of time for every  $l$  buffers from 1 to  $l$  all together contain at most  $2^{l-1}$  elements

## Discussion

Comments on final solution:

- Cost:  $O(t \cdot (\log t)^3)$  time,  $O(m \cdot (\log m)^2)$  memory
- Omitted details: realization of oblivious hashing and random oracle
- Tamper-proofing extension

## Home Problem 4

Prove that the chance of overflow in hash table construction is less than  $1/m$

## Summary

Main points:

- Theoretical model for hardware-based code protection: **open memory/protected CPU**
- Central problem: simulation of any program with any input by the **same access pattern**
- Current result:  $O(t \cdot (\log t)^3)$  time,  $O(m \cdot (\log m)^2)$  memory simulation
